Topic of the Lecture

Your name

ISEG Lisbon School of Economics & Management

May 2, 2020

Contents

- ① Introduction
 - ▶ Before we start
 - ▶ Environments
- ② Some formulas
 - ▶ Multinomial - Dirichlet Model
 - ▶ Binomial - Beta Model
- ③ Code chunks
 - ▶ Python code
 - ▶ R code

About this lecture

In this lecture you will see:

- a graph
- some formulas
- some code
- some customized environments
- some citations (Kass and Raftery, 1995)
- a link to [ISEG's](#) website

Some useful fonts

- you can use **bold** font
- you can also use *italics*
- the typewriter font can also be useful

A scatterplot

This picture is in the “figures” folder:

Figure 1: Fuel consumption (Hwy) vs engine size (displ)

Three ways to make citations

- Kass and Raftery, 1995
- (Kass and Raftery, 1995)
- Kass and Raftery (1995)

Definitions and theorems

I customized the definition theorem and block environments:

Definition (Fibration)

A fibration is a mapping between two topological spaces that has the homotopy lifting property for every space X .

Theorem (Bayes)

$$P(\theta|\mathbf{D}) = P(\theta) \frac{P(\mathbf{D}|\theta)}{P(\mathbf{D})}$$

The block environment

The block environment is more versatile. You can write whatever you want on the red block:

Pythagorean theorem

This is a theorem about right triangles and can be summarised in the next equation

$$x^2 + y^2 = z^2$$

Corollary

There's no right rectangle whose sides measure 3cm, 4cm, and 6cm.

Two part functions

I also included an environment that allows you to easily write two part functions:

$$|x| = \begin{cases} x & \text{if } x \geq 0 \\ -x & \text{if } x < 0 \end{cases}$$

Bayesian stuff

- Likelihood: $\mathbf{x}|\boldsymbol{\theta} \sim \mathcal{M}_k(N, \boldsymbol{\theta})$
- Hypotheses: $H_0 : \boldsymbol{\theta} = \boldsymbol{\theta}_0$ vs $H_1 : \boldsymbol{\theta} \neq \boldsymbol{\theta}_0$
- Prior: $\pi(\boldsymbol{\theta}|H_0) = 1_{\boldsymbol{\theta}_0}(\boldsymbol{\theta}_0)$ and $\boldsymbol{\theta}|H_1, \boldsymbol{\alpha} \sim \text{Dir}_k(\boldsymbol{\alpha})$
- Marginal density: $m_i(\mathbf{x}) = \int_{\Theta_i} f(\mathbf{x}|\boldsymbol{\theta})\pi(\boldsymbol{\theta}|H_i) d\boldsymbol{\theta}$, $i = 0, 1$

$$\blacktriangleright m_0(\mathbf{x}) = \frac{N!}{\prod_{i=1}^{k+1} x_i!} \prod_{i=1}^{k+1} \theta_{0i}^{x_i}$$

$$\blacktriangleright m_1(\mathbf{x}) = \frac{N!}{\prod_{i=1}^{k+1} x_i!} \frac{B(\boldsymbol{\alpha} + \mathbf{x})}{B(\boldsymbol{\alpha})}$$

- Bayes factor:

$$B_{01}(\mathbf{x}) = \frac{m_0(\mathbf{x})}{m_1(\mathbf{x})} = \frac{\prod_{i=1}^{k+1} (\theta_{0i}^{x_i}) \prod_{i=1}^{k+1} [\Gamma(\alpha_i)] \Gamma[\sum_{i=1}^{k+1} (\alpha_i + x_i)]}{\Gamma(\sum_{i=1}^{k+1} \alpha_i) \prod_{i=1}^{k+1} \Gamma(\alpha_i + x_i)}$$

- For an interesting application see Pericchi and Torres (2011).

Bayesian stuff

- Prior: $\theta|\alpha \sim \text{Dir}_k(\alpha)$
- Posterior: $\theta|\alpha, \mathbf{x} \sim \text{Dir}_k(\alpha + \mathbf{x}) \rightarrow$ Mean, mode, credible intervals.
- For an interesting application see Ley (1996).

More Bayesian stuff

- Likelihood: $x \sim \text{Bin}(N, \theta)$
- Hypotheses: $H_0 : \theta = \theta_0$ vs $H_1 : \theta \neq \theta_0$
- Prior: $\pi(\theta|H_0) = 1_{\theta_0}(\theta)$ and $\theta|H_1 \sim \text{Beta}(a, b)$
- Marginal density: $m_i(x) = \int_0^1 f(x|\theta)\pi(\theta|H_i)d\theta, i = 0, 1$
 - ▶ $m_0(x) = \binom{N}{x} \theta_0^x (1 - \theta_0)^{N-x}$
 - ▶ $m_1(x) = \binom{N}{x} \frac{B(x+a, n-x+b)}{B(a, b)}$
- Bayes factor: $B_{01}(x) = \frac{m_0(x)}{m_1(x)} = \frac{\theta_0(1-\theta_0)^{N-x} \Gamma(a) \Gamma(b) \Gamma(n+a+b)}{\Gamma(a+b) \Gamma(n+a-x) \Gamma(x+a)}$

More Bayesian stuff

- Prior: $\theta \sim \text{Beta}(a, b)$
- Posterior: $\theta|x \sim \text{Beta}(a + x, b + N - x) \rightarrow \text{Mean, mode, credible intervals}$

Python code looks good on verbatim

This code prints the Fibonacci sequence:

```
nterms = int(input("How many terms? "))
n1, n2 = 0, 1
count = 0
print("Fibonacci sequence:")
while count < nterms:
    print(n1)
    nth = n1 + n2
    n1 = n2
    n2 = nth
    count += 1
}
```

Some R code

I also included a verbatim environment with background color:

```
getmode <- function(v) {  
  uniqv <- unique(v)  
  uniqv[which.max(tabulate(match(v, uniqv)))]  
  
}
```

With this R code you can build a function that calculates the mode.
